

# Report on FI studies with PEPSI

R. Debbe BNL

We have resumed the generation of  $e^+p$  events with the PEPSI Monte-Carlo.

I have generated 10M events per setting for 4X50, 4X100 and 4X250 (EeXEp). That is equivalent to 3 weeks of running MeRHIC at  $L = 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$  and a cross section for inclusive DIS of 0.4 micro barn.

The information stored in the root trees filled with output from PEPSI is transferred to a program that bins  $x$ ,  $Q^2$  and  $y$  and fits the values of reduced cross section as function of  $y$ . Those plots are fit to straight line and  $F_2$  is the intercept and  $F_1$  the slope.

$F_L$  values without conditions on the statistical error. Useful only to show rough coverage of the measurement.

Relative statistical error for ~6M  
events transferred to root trees.

The next step consist on displaying many more intermediate steps, from generation to extraction of Fl. (Validation).

Next I plan to work on introducing detector resolution. (smear  $x$   $Q^2$  and  $y$  with Gaussian distributions and extract Fl.) (Do I have to recalculate cross sections?)

Turn on radiation corrections in the Monte-Carlo and repeat extraction of Fl.
